Note: Within nine months from the publication of the mention of the grant of the European patent, any person may give notice to the European Patent Office of opposition to the European patent granted. Notice of opposition shall be filed in a written reasoned statement. It shall not be deemed to have been filed until the opposition fee has been paid. (Art. 99(1) European patent convention).

## Description

This invention relates to novel compositions useful as mortar for the installation of ceramic wall and floor tiles. More specifically, it relates to such a composition containing a novel water-retention agent.

- 5 Conventional ceramic tile cements are mixtures of cement, sand, and thickener, usually, they also contain small amounts of polyacrylamide and polyvinyl alcohol to improve performance. The dry cement mixture is then mixed with water to form a mortar.

The physical characteristics of a cured conventional mortar are determined by the rate of curing, and thus, by the rate of water removal therefrom during the curing operation. Any influence which affects these parameters by increasing the rate of water removal or by diminishing the water concentration in the mortar at the onset of the curing reaction can cause a deterioration of the physical properties of the mortar. Most ceramic wall tiles, on their unglazed surfaces, are highly porous and, when set on such a mortar, absorb water therefrom, leading to the difficulties just mentioned. Likewise, most strata to which these tiles are applied such as wallboard, cinderblock, or masonry, are also porous and lead to the same problems.

- 15 To overcome, or at least minimize, the above-mentioned water-loss problems, it has been suggested to add to the mortar compositions a small amount of a water-soluble polymer, such as, methylcellulose (U.S. Pat. No. 2,934,932); hydroxyethyl cellulose (U.S. Pat. No. 3,243,307); or phenyl hydroxyethyl cellulose, benzyl hydroxyethyl cellulose or ethyl hydroxyethyl cellulose (U.S. Pat. No. 4,065,319) as a water retention aid. These polymers prevent escape of the water from the cement by increasing the viscosity of the water

20 phase, thus, maintaining the desired water concentration in the mortar during curing.

In accordance with this invention, it has been found that a dry mortar-forming composition comprising, by weight, from about 24% to about 99% of hydraulic cement, from about 0% to about 75% sand, and from about 0.3% to about 4% of a water-retaining thickener, which dry composition is capable, when mixed with from about 25% to about 40% of its own weight of water, of producing a mortar which

- 25 can be applied in thin layers for setting tile on walls and ceilings, is improved by using a modified hydroxyethyl cellulose having a hydroxyethyl substitution from about 0.3 to about 4.0 M.S. and a hydroxypropyl substitution greater than 0.35 M.S. as the water-retention aid or thickener. More than 0.35 hydroxypropyl M.S. is required to lower the set time of the mortar to the desired level. Preferably the hydroxypropyl substitution is greater than 0.6 M.S. Most preferably, the hydroxyethyl M.S. will be from

30 about 0.8 to 1.8, and the hydroxypropyl M.S. will be from about 0.8 to about 1.5.

The designation M.S. refers to the average number of moles of hydroxyethyl or hydroxypropyl substituent groups combined per cellulosic anhydroglucose unit.

- Typically from about 0.3% to about 4% of the modified hydroxyethyl cellulose or of blends thereof is used.
- 35 When compared with the mortars prepared with conventional hydroxyethyl celluloses as the water retention agent, the mortars of this invention are improved in texture, set times, and adjustability times, which are three important parameters used widely in the art to characterize tile mortars. They also show improvement in tack and cohesiveness.

40 Set time is defined in ASTM C266-65. Basically set time is the time the mortar takes to set or harden at a given thickness. Adjustability time is the time during which the position of the tile on the wall can be changed without the tile coming loose from the mortar.

- The modified hydroxyethyl cellulose which can be used as thickener in the mortars of this invention is prepared by reacting ethylene oxide and propylene oxide with cellulose in a strongly alkaline medium. Specific techniques for carrying out the etherification are well known in the art and any known procedure

45 can be employed.

In the alternative, a hydroxyethyl cellulose can be etherified with a propylene oxide in a strongly alkaline medium. In this case, the hydroxyethyl cellulose can be substantially any grade having M.S. from about 0.3 to about 4.0. The preferred materials are those having a viscosity from about 800 to about 5000 centipoise (mPas) in a 1% water solution. Materials of higher and lower viscosity can also be used

- 50 advantageously, however.
- A tile mortar based on Portland cement or other hydraulic cements can be prepared containing only the hydraulic cement and the water retention aid of the present invention. Normally, however, most formulations will include a rather substantial amount of sand.
- The amount of hydraulic cement can be as high as 99.4% in the case of a mortar containing only

55 hydraulic cement and the modified hydroxyethyl cellulose to as little as about 24% of the hydraulic cement in the case of mortars containing sand and other components. Sand, if used, should be present in the amount of from one to three volumes of sand per volume of hydraulic cement. For setting porous tiles, a mixture containing equal volumes of hydraulic cement and sand up to one volume of hydraulic cement per 1 1/2 volumes of sand produces a mortar which is entirely satisfactory.

- 60 The dry mortar composition may also contain finely divided inorganic or organic fibers, such as, for example, mineral wool, glass fibers, fibrous (low substitution or crosslinked) carboxymethyl cellulose, and the like, in amount of from about 1% to about 2%. The incorporation of the fibers improves the thixotropic properties of the mortar, i.e., the use of fibers prevent sag of the mortar. Using a mortar containing fibers to bond ceramic tile to a vertical wall lessens the tendency of the tile to slip down the wall during setting of the mortar. More commonly, a small amount of polyacrylamide or of an anionic or cationic copolymer of

acrylamide, i.e., about 1% based by weight on the thickener, is used to improve sag resistance. Polyvinyl alcohol in small amount, from about 0.05% to about 2%, based on the weight of the hydraulic cement, is frequently included to increase wet adhesion and attain better workability.

Thus, the hydraulic cement dry mixture of this invention consists essentially of from about 24% to about 99.4% hydraulic cement; from about 0.3% to about 4% of the modified hydroxyethylcellulose or of blends thereof; and from about 0% to about 75% sand.

This dry mixture, when added to water, forms a thin-set mortar, i.e., a mortar which can be used in thin layers on the order of 3.18 to 6.35 mm (1/8 to 1/4 inch). The amount of water used is such that the resultant mixture will not be so thin as to slide down a wall or drop off a ceiling when applied. In general, from about 25% to about 50% water, by weight based on the weight of the dry mixture, gives good results.

In the examples which follow, various embodiments of the mortar compositions of this invention are illustrated. In Examples 1 through 11, the formulation shown in Table I is employed except that a hydroxypropyl hydroxyethyl cellulose having the hydroxyethyl M.S. and the hydroxypropyl M.S. shown in Table II for the particular example in question is used as the thickener.

TABLE I

Components	Parts by weight
White Portland cement	48.89
Fine sand	50.3
Polyacrylamide	0.01
Thickener	0.6
Polyvinyl alcohol	0.2
Water	26.0*

\*By weight of the dry component mixture.

The mortar compositions of this invention are prepared by dry mixing the first five components of Table I to a substantially homogeneous state, adding the dry mix to the water, and manually stirring to obtain a trowelable mix with complete and visually uniform wetting of the dry components. The wet mass is slaked for 30 minutes (except for that portion to be used in the set time test which is slaked for only 10 minutes), then remixed thoroughly before any evaluations are carried out.

A portion of the mortar is troweled onto the vertical surface of a dry cinderblock between guide strips 6.35 mm (1/4 inch) thick. A Type B (floor) ceramic tile is lightly tapped onto the mortar surface immediately after application to the cinderblock with the back ribs of the tiles in vertical alignment. The position of the top edge of the tile is marked. Sag is the downward displacement of the tile measured 2 hours after placement on the mortar surface.

After another hour of slaking the mortar is troweled at room temperature and about 50% relative humidity (R.H.) onto a section of gypsum wallboard and 10 Type A (wall) ceramic tiles are pressed onto the mortar leaving 1.59 mm (1/16 inch) spacing between the tiles and wallboard. At 5-minute intervals at room temperature, a tile is twisted through a 90° angle back to its original position. Adjustability time is the longest time at which a tile remains affixed to the mortar when tested in this manner. The characteristics of the cement are shown in Table II.

Set time is the time mortar applied to a ceramic tile at a given thickness takes to set or harden as measured by a Gilmore needle according to the procedures of ASTM C266-65.

Consistency, tack, and cohesiveness are subjective tests which measure trowelability, how well the mortar sticks to a metal spatula or trowel, and the overall integrity of the mortar composition, respectively.

Features, advantages and other specific embodiments of this invention will become readily apparent to those exercising ordinary skill in the art after reading the foregoing disclosures.

**Claims for the Contracting States: BE CH DE FR GB IT LI NL SE**

- 5 1. A dry mortar-forming composition which comprises, by weight, from about 24% to about 99% of hydraulic cement, from about 0% to 75% sand and from about 0.3 to about 4% of a water-retaining thickener, said dry composition being capable, when mixed with from about 25% to about 40% of its own weight in water, of producing a mortar which can be applied in thin layers for setting tile on walls and  
10 ceilings, characterized in that the water-retaining thickener is at least one modified hydroxyethyl cellulose having hydroxyethyl M.S. from about 0.3 to about 4.0 and hydroxypropyl M.S. greater than 0.35.
2. The composition of claim 1 wherein the modified hydroxyethyl cellulose has a hydroxypropyl M.S. greater than 0.6.
3. The composition of claim 1 wherein the modified hydroxyethyl cellulose has a hydroxyethyl M.S.  
15 from about 0.8 to about 1.8 and a hydroxypropyl M.S. from about 0.8 to about 1.5.
4. The composition of claim 1 which further comprises about 1%, based by weight on the thickener, of a polymer selected from the group consisting of polyacrylamide and anionic or cationic copolymers of acrylamide.
5. The composition of claim 1 which further comprises from about 0.05% to about 2%, based by weight  
20 on the hydraulic cement, of a polyvinyl alcohol.
6. The composition of claim 2 which further comprises about 1%, based by weight on the thickener, of a polymer selected from the group consisting of polyacrylamide and anionic or cationic copolymers of acrylamide.
7. The composition of claim 2 which further comprises from about 0.05% to about 2%, based by weight  
25 on the hydraulic cement, of a polyvinyl alcohol.
8. The composition of claim 3 which further comprises about 1%, based by weight on the thickener, of a polymer selected from the group consisting of polyacrylamide and anionic or cationic copolymers of acrylamide.
9. The composition of claim 3 which further comprises from about 0.05% to about 2%, based by weight  
30 on the hydraulic cement, of a polyvinyl alcohol.

**Claims for the Contracting State: AT**

1. A process of producing a mortar which can be applied in thin layers for setting tiles on walls and  
35 ceilings, wherein a dry composition, which comprises, by weight, from about 24% to about 99% of hydraulic cement, from about 0% to 75% sand and from about 0.3 to about 4% of a water-retaining thickener, is mixed with from about 25% to about 40% of its own weight of water, characterised in that the water-retaining thickener is at least one modified hydroxyethyl cellulose having hydroxyethyl M.S. from  
40 about 0.3 to about 4.0 and hydroxypropyl M.S. greater than 0.35.
2. The process of claim 1 wherein the modified hydroxyethyl cellulose has a hydroxypropyl M.S. greater than 0.6.
3. The process of claim 1 wherein the modified hydroxyethyl cellulose has a hydroxyethyl M.S. from  
about 0.8 to about 1.8 and a hydroxypropyl M.S. from about 0.8 to about 1.5.
4. The process of claim 1 in which the composition further comprises about 1%, based by weight on  
45 the thickener, of a polymer selected from the group consisting of polyacrylamide and anionic or cationic copolymers of acrylamide.
5. The process of claim 1 in which the composition further comprises from about 0.05% to about 2%, based by weight on the hydraulic cement, of a polyvinyl alcohol.
6. The process of claim 2 in which the composition further comprises about 1%, based by weight on  
50 the thickener, of a polymer selected from the group consisting of polyacrylamide and anionic or cationic copolymers of acrylamide.
7. The process of claim 2 in which the composition further comprises from about 0.05% to about 2%, based by weight on the hydraulic cement, of a polyvinyl alcohol.
8. The process of claim 3 in which the composition further comprises about 1%, based by weight on  
55 the thickener, of a polymer selected from the group consisting of polyacrylamide and anionic or cationic copolymers of acrylamide.
9. The process of claim 3 in which the composition further comprises from about 0.05% to about 2%, based by weight on the hydraulic cement, of a polyvinyl alcohol.
